

Inheritance and polymorphism

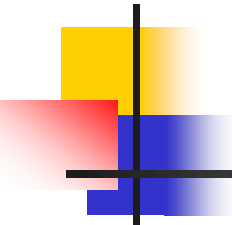

❑ Inheriting Variable in a class

- Inheritance “It is an activity of an deriving a new class from a n old class ”
- We use the concept of inheritance to achieve significance of code reuse
- Base class / parent class / super class concept
- Derived class / subclass / child class concept.
- We can Inherit all the instance variable from Super class
- We shall also define new instance variable in the subclass
- If Newly define variable name are same variable name in super class it , shadows the super class variable

- 
- Use the *extends* keyword to inherit the functionality and features from super class to subclass

e.g.

```
class A {  
    --- ;  
    statements;  
    --- ;  
}  
class B extends A  
{  
    --- ;  
    Statements ;  
    --- ;  
}
```

□ Inheriting the method in a class

- When we define methods for a subclass
